Abstract
A computation of the electron mass is found utilizing a generalized holographic approach in terms of quantum electromagnetic vacuum fluctuations. The solution gives a clear insight into the structure of the hydrogen Bohr atom, in terms of the electron cloud and its relationship to the proton and the Planck scale vacuum fluctuations. Our electron mass solution is in agreement with the measured CODATA (Committee on Data of the International Council for Science) 2014 value. As a result, an elucidation of the source of the fine structure constant, the Rydberg constant and the proton-to-electron mass ratio is determined to be in terms of vacuum energy interacting at the Planck scale.

Keywords
Electron; Hadron Mass; Holographic; Quantum Gravity; Entropy

1. Introduction

The electron mass is typically determined utilizing penning traps, where measurements of the cyclotron frequency for both an electron and a reference ion can be made. The latest measured value given by the Committee on Data for Science and Technology (CODATA) is $9.10938356(11) \times 10^{-28}$ g with a relative uncertainty of $1.2 \times 10^{-8}$ [1]. More recent indirect methods, combine Penning trap measurements of the Larmor-to-cyclotron frequency ratio with a corresponding very accurate electron spin g-factor calculation and find the more precise values of $0.000548579909067(14)(9)(2)$ u $(9.109389919 \times 10^{-28} \text{ g})$ and $0.000548579909065(16)$ u $(9.109389919 \times 10^{-28} \text{ g})$, respectively, with a relative uncertainty of order $10^{-11}$ [2] [3].

These measurements are extremely precise, and yet a satisfactory derivation from first principles remains to be found and thus the nature of the electron remains a mystery.

The standard definition for the mass of the electron is therefore generally given in terms of the Rydberg constant $R_e$,

$$m_e = \frac{2R_e h}{c \alpha^2} = 9.10938356(11) \times 10^{-28} \text{ g}$$  \hspace{1cm} (1)

where $h$ is Planck’s constant and $\alpha$ is the fine structure constant.

† Presented at the 4th Annual International Symposium on Physics, 18-21 July 2016, Athens Institute for Education and Research
The electron and the holographic mass solution

However, although in agreement with the measured CODATA 2014 value, this standard form does not reveal the nature or structure of the electron. As noted by Frank Wilczek, “An electron’s structure is revealed only when one supplies enough energy […] at least 1 MeV, which corresponds to the unearthly temperature of \(10^{10}\) kelvin” below which it ‘appears’ point-like and structure-less [4].

Although the position and momentum can only be defined in terms of a probability cloud, the quantum behavior of the electron is successfully calculated by the current standard model. Yet the most precise prediction, being that of the g-factor [5] [6], still requires the inclusion of a contribution from quantum vacuum fluctuations [7] to account for the observed deviation known as the anomalous magnetic moment [8].

Quantum corrections are also expected for an electric field – but as yet no such field has been detected. Based on charge-parity (CP) violating components the standard model assumes an upper limit on the electron electric dipole moment (EDM) of \(d_e \leq 10^{-38}\) cm, [9] which is smaller than current experimental sensitivities. However recent experiments confirm a non-zero EDM with a much higher upper limit e.g. [10], [11] and more recently [12] who find \(d_e < 10.5 \times 10^{-28}\) cm \(d_e < 6.05 \times 10^{-25}\) cm and \(d_e < 1.1 \times 10^{-29}\) cm, respectively, suggesting the standard model is incomplete and there must be other sources of CP violation. Higher EDMs are predicted by extensions to the standard model e.g. supersymmetric models, which predict \(d_e > 10^{-26}\) cm [13], and are in agreement with the results from [11] but not [10] and [12]. In either case it is clear that current models, the standard model and extensions such as supersymmetric models, are incomplete.

Defining the fundamental characteristics of particles from first principles, and without free parameters, is of great importance as not only will it provide information about the structure of subatomic particles but also the source of mass and the nature of spacetime itself. Successful predictions allow us to confirm and improve upon existing models.

In the standard approach, quantum chromodynamics (QCD), hadron masses are determined by considering not only the quark masses but as well and most importantly the dynamics of the system. Due to the non-linear nature of the strong force, exact calculations of nucleons and their constituent parts are extremely difficult and thus rely on numerical techniques where probability amplitudes are assigned to each Feynman diagram and monte carlo simulations (or other similar iterative methods) determine the best fit. However, despite the development of sophisticated numerical techniques and ever faster super computers, QCD calculations have been unable to successfully predict the mass of the proton.

In an effort to make a reasonable prediction, Durr et al. (2008) [14] utilized a computational technique called lattice gauge theory. In the lower energy regime (i.e. lower than proton energy) where the interactions are strong, and the coupling parameter is large [15], a non-perturbative approach is required where a discrete set of spacetime points rather than a spacetime continuum allows for improved calculations. In the model used by Durr et al. (2008) [14], only three input parameters were required: the light (up and down) quark mass; the strange quark mass; and the gauge coupling parameter, \(g\). These calculations cannot distinguish between a proton or a neutron and thus yield a general value for a nucleon of \(m_N = 936 MeV/c^2 \pm 25 / \pm 22 = 1.67 \times 10^{-24} \pm 0.0446\) g [1]. This value is in good agreement with the general mass of a nucleon but, based on the time-intensive methods, is not yet as
good as expected. Furthermore, there is no analytical solution to LQCD or a good understanding on the nature of confinement. There is no doubt that QCD is successful at calculating these measured parameters, however, as noted by Wilczek [16], there are limitations to the purely mathematical approach of QCD, and he thus suggests, along with the asymptotic method, a more simplistic approach which looks at the underlying physical model.

Starting with the premise that an electron cloud can be considered as an ‘electron’ coherent field of information we look at the microstructure of the electron system from a generalised holographic approach. In the next section, we will give an overview of this generalised holographic approach, which in previous work successfully computes the mass of the proton [17] and a precise charge radius of the proton within an 1σ agreement with the latest muonic measurements [18], relative to a 7σ variance in the standard approach [19].

Utilizing this approach, we find an electron mass solution in terms of the surface-to-volume entropy measured as Planck oscillator information bits. This value is in agreement with the measured CODATA 2014 value.

2. The holographic principle and the proton mass

In previous work [17] [18], a quantized solution to gravity is given in terms of Planck Spherical Units (PSU) in a generalized holographic approach. This section gives a brief overview of the generalised holographic approach, for a more detailed description please see the previous publications [17] [18].

The Bekenstein conjecture, first suggested by Jacob Bekenstein in the early 1970’s, proposed that the entropy $S$ or information contained in a given region of space, such as a black hole, is proportional to its surface horizon area [20] [21] [22]. Based on the laws of thermodynamics and the prediction of Hawking radiation, Hawking inferred and subsequently set the constant of proportionality to be $\frac{1}{4}$ of the surface horizon [23]. The Bekenstein-Hawking entropy of a black hole expressed in units of Planck area is thus given as,

$$S = \frac{A}{4\ell^2} \quad (2)$$

where the Planck area, $\ell^2$ is taken as one unit of entropy and $A$ is the surface area of the black hole.

Bekenstein [24] further argued for the existence of a universal upper bound for the entropy of an arbitrary system with maximal radius $r$,

$$S \leq \frac{2\pi rE}{hc} \quad (3)$$

and found that this maximal bound is equivalent to the Bekenstein-Hawking entropy for a black hole (assuming $E = mc^2$). This confirmed the long suspected assumption that black holes have the maximum entropy for a given mass and size, which along with unitarity
arguments led to the holographic principle of ‘t Hooft, where one bit of information is encoded by one Planck area [25] [26].

Following the holographic principle of ‘t Hooft [26], based on the Bekenstein-Hawking formulae for the entropy of a black hole [27] [28], the surface and volume entropy of a spherical system is explored [17] [18]. The holographic bit of information is defined as an oscillating Planck spherical unit (PSU), given as,

\[ PSU = \frac{4}{3} \pi r_s^3 \]  

(4)

where \( r_s = \frac{\ell}{2} \) and \( \ell \) is the Planck length.

These PSUs, or Planck voxels, tile along the area of a spherical surface horizon, producing a holographic relationship with the interior information mass-energy density.

**Figure 1.** schematic to illustrate the Planck Spherical Units (PSU) packed within a spherical volume.

In this generalized holographic approach, it is therefore suggested that the information/entropy of a spherical surface horizon should be calculated in spherical bits and thus defines the surface information/entropy in terms of PSUs, such that,

\[ \eta = \frac{A}{\pi r_s^2} \]  

(5)

where the Planck area, taken as one unit of information/entropy, is the equatorial disk of a Planck spherical unit, \( \pi r_s^2 \) and \( A \) is the surface area of a spherical system. We note that in
this definition, the entropy is slightly greater (~ 5 times) than that set by the Bekenstein Bound (Eqn. 3), and the proportionality constant is taken to be unity (instead of 1/4 as in the Bekenstein-hawking entropy). It has been previously suggested that the quantum entropy of a black hole may not exactly equal $A/4$ [29]. To differentiate between models, the information/entropy $S$, encoded on the surface boundary in Haramein’s model is termed, $\eta \equiv S$.

As first proposed by ‘t Hooft the holographic principle states that the description of a volume of space can be encoded on its surface boundary, with one discrete degree of freedom per Planck area, which can be described as Boolean variables evolving with time [25]. Following this definition for surface information $\eta$, the information/entropy within a volume of space is similarly defined in terms of PSU as,

$$R = \frac{V}{\frac{4}{3}\pi r^3} = \frac{r^3}{r_i^3}$$

(6)

where $V$ is the volume of the spherical entity and $r$ is its radius.

In previous work [17] [18] it was demonstrated that the holographic relationship between the transfer energy potential of the surface information and the volume information, equates to the gravitational mass of the system. It was thus found that for any black hole of Schwarzschild radius $r_i$ the mass $m_s$ can be given as,

$$m_s = \frac{R}{\eta} m_i$$

(7)

where $m_i$ is the Planck mass, $\eta$ is the number of PSU on the spherical surface horizon and $R$ is the number of PSU within the spherical volume. Hence, a holographic gravitational mass equivalence to the Schwarzschild solution is obtained in terms of a discrete granular structure of spacetime at the Planck scale. It should be noted that this view of the interior structure of the black hole in terms of PSUs, is supported by the concept of black hole molecules and their relevant number densities as proposed by Miao and Xu [30] and Wei and Lui [31]. As well, the relationship between the interior structure in terms of ‘voxels’ and the connecting horizon pixels is discussed in the work of the work of Nicolini [32].

Furthermore, this inequality in energy potential between the surface information and the volume information, where $R > \eta$ for all $r > 2\ell$ suggests that both, the gravitational curvature potential is the result of an asymmetry in the information structure of spacetime, and the volume information is not only the result of the information/entropy surface bound of the local environment but may also be non-local, due to wormhole interactions as those proposed by the ER=EPR conjecture, where black hole interiors are connected through micro wormhole interactions [33].

Moreover, we find that the only radius at which the holographic ratio equals one (i.e. $R = \eta$), where all the volume information is encoded on the surface, is the condition
The electron and the holographic mass solution

\[ r_{s_e} = \frac{2Gm_e}{c^2} = 2\ell \]  

(8)

where \( r_{s_e} \) is the Schwarzschild radius of a black hole with mass \( m = m_e \).

In this case, the surface entropy \( \eta \) and the volume entropy \( R \) are thus calculated to be,

\[ \eta_e = \frac{4\pi r_{s_e}^2}{\pi r_e^2} = \frac{4\pi(2\ell)^2}{\pi(\ell/2)^2} = 64 \]  

(9)

\[ R_e = \frac{r_{s_e}^3}{r_e^3} = \left( \frac{2\ell}{\ell/2} \right)^3 = 64 \]  

(10)

This results in a holographic ratio of \( R_e/\eta_e = 1 \) yielding \( m_e = \frac{R_e}{\eta_e}m_f \), such that a balanced state of equilibrium between the volume-to-surface information transfer potential is achieved, supporting the conjecture that due to its ultimate stability, the Planck entity is the fundamental granular kernel structure of spacetime forming a crystal-like structured lattice at the very fine scale of the quantum vacuum [34] [35].

Additionally, it is important to note that there is a factor of 2 or \( \frac{1}{2} \) between the Planck length and the Schwarzschild radius of a Planck mass black hole, and although its physical meaning has yet to be completely understood, it has been related to geometric considerations of motion, particle physics and cosmology, and commonly occurs in the most fundamental equations of physics [36]. However, the origin of this factor may be the result of the holographic surface-to-volume consideration of the fundamental geometric clustering of the structure of spacetime at the Planck scale, where one Planck mini black hole is a cluster bundle of Planck spherical vacuum oscillators [37].

Of course, these considerations on the granular structure of space lead to the exploration of the clustering of the structure of spacetime at the nucleonic scale, where it was found that a precise value for the mass \( m_p \) and charge radius \( r_p \) of a proton can be given as,

\[ m_p = 2\frac{\eta}{R}m_e = 2\phi m_e \]  

(11)

\[ r_p = 4\ell \frac{m_{s_e}}{m_p} = 0.841236(28)\times10^{-13} cm \]  

(12)

where \( \phi \) is defined as a fundamental holographic ratio. Significantly, this value is within an \( 1\sigma \) agreement with the latest muonic measurements of the charge radius of the proton [17] [18], relative to a \( 7\sigma \) variance in the standard approach [19].

The radius of an oscillating electrostatic field such as a proton defines an effective charge boundary in that region of space – a ‘charge radius’. The standard approach thus relies on indirect measurements of the energy interaction at the charge surface boundary between the
electron and the proton when measuring the Lamb shift quantum vacuum oscillations [38] [39] [40] [41] [42]. This is typically done utilizing electron proton scattering and/or hydrogen spectroscopy methods. Both these methods have consistently yielded similar results, where the latest 2014 CODATA value, \( r_p = 0.8751(61) \times 10^{-13} \text{cm} \), is based on a least-squares approximation between both methods.

3. Determining the mass of the electron

In the previous section we described a generalized holographic solution which derives the proton mass from the granular Planck scale structure of spacetime in terms of a surface-to-volume information transfer potential.

The question is – can this approach be extended to the electron? The first step in answering this question is to consider the spatial extent of the electron and the volume of information that it encloses. However, the spatial extent of the electron hasn’t been conclusively defined. As we described in section 2, the generalized holographic model sees the mass as emerging from the granular Planck scale structure of spacetime in terms of a surface-to-volume information transfer potential \( \phi \), which decreases with increasing radius. Similarly, instead of thinking about the electron as a separate system, the electron could be thought of as a cloud of potential energy spatially extending from the proton out to the radius where the volume encloses the electron cloud of a hydrogen Bohr atom. Thus, in an attempt to deepen our understanding, we consider the holographic ratio relationship as we extend the radius of the co-moving Planck particles to \( r > r_p \).

Equation 11, therefore becomes,

\[
m_r = \beta \phi r m_i
\]

where \( m_i \) is the mass of any spherical system with radius \( r \), \( \beta \) is a geometric parameter, and \( \phi \) is the holographic surface-to-volume ratio in terms of PSU for any spherical system with radius \( r \).

With \( \beta = 1/2 \alpha \) (refer to previous section on the factor of 2 in physics), we find a mass in precise agreement with the experimental mass of the electron when the holographic ratio reaches \( r = a_0 \), where \( a_0 \) is the Bohr radius.

The solution for the mass of the electron can thus be given as,

\[
m_e = \frac{1}{2\alpha} \phi m_i
\]

where
The electron and the holographic mass solution

\[ \phi_e = \frac{\eta_e}{R_e}, \quad \eta_e = \frac{4\pi a_0^2}{\pi r_e^2}, \quad \text{and} \quad R_e = \frac{4/3 \pi a_0^3}{4/3 \pi r_e^3} \]

With this solution we find a mass of, \( m_e = 9.10938(30) \times 10^{-28} \text{g} \), which compared to the measured CODATA 2014 value is accurate within \( 1\sigma \) and with a precision of \( 10^{-8} \) [1]. The precision and thus accuracy of our solution is restricted by the value of the Planck units which are dependent on experimental values given for the Gravitational constant, \( G \). However, when the absolute value for the holographic mass solution for the electron is considered the mass is comparable with the experimental CODATA 2014 value to a greater degree of accuracy < \( 1\sigma \) and a precision of \( 10^{-8} \) with a confidence level of 99.999%.

The presence of \( \alpha \) in equation 14, reveals that both the charge and velocity are important contributing factors to the mass solution where, for the case of the electron at least, the holographic mass solution can be formulated in terms of both velocity and charge relationships,

\[ m_e = \frac{1}{2\alpha} \frac{\phi_e m_i}{2 \frac{v}{v_e} \phi_i m_i} = \frac{1}{2} \frac{a_0^2}{2 q_e^2} \phi_i m_i \]

where \( \alpha = \frac{v_i}{v_e} \) and \( \alpha = \frac{q_i}{q_e} \).

This solution, as well as being significantly accurate, gives us insight into the physical and mechanical dynamics of the granular Planck scale vacuum structure of spacetime and its role in the source of angular momentum, mass and charge. The definition clearly demonstrates that the differential angular velocities of the collective coherent behavior of Planck information bits (PSU) determines specific scale boundary conditions and mass-energy relationships, analogous to the collective behavior of particles in a rotating fluid [43] or superfluid plasma [44].

This solution, as well resolves the difficulty associated with hierarchy problems (we will address the electron-to-proton mass ratio below). The current quantum understanding resolves the hierarchy bare mass problem for the electron mass through the consideration of antimatter where positron and electron pairs pop in and out of the vacuum. These virtual particles smear out the charge over a greater radius such that the bare mass energy is cancelled by the electrostatic potential, where the greater the radius the lesser the need for fine tuning. In the solution presented here the electron is extended to a maximal radius of \( a_0 \) and we are able to demonstrate that the mass of the electron is a function of the Planck vacuum oscillators surface-to-volume holographic relationship, over this region of spacetime. The hierarchy bare mass problem is thus resolved by considering Planck vacuum oscillators acting coherently extending over a region of space equivalent to the Bohr hydrogen atom. In much the same way that the electron analogy is proposed to resolve the Higgs hierarchy problem, with the inclusion of virtual supersymmetric particles, we could also assume that the surface-to-volume holographic relationship in the Higgs region of space would solve for the mass of the Higgs, where the Higgs radius would be of the order, \( r_i < r_{\text{Higgs}} < r_p \).
The electron and the holographic mass solution

The hierarchy problem associated with the mass of the electron and the mass of the proton can also be understood in terms of the surface-to-volume holographic ratio over their respective commoving regions of space, where the greater the radius the smaller the mass. The mass is thus a direct function of the commoving behaviour of the Planck vacuum, where the spin and mass decrease as a function of increasing radius.

4. Extension of the holographic solution for radii less than the Bohr radius

When we further extend this solution for the n=1 state we find that, at radii $r < a_0$, the holographic mass solution increases as shown in Figure 3. This application of the holographic solution gives us the following equation,

$$\frac{1}{2\alpha} \phi_r(r)m_e = Nm_e$$

where $\phi_r(r)$ is the holographic ratio as a function of the radius $r$ for $r < a_0$, and $N$ is an integer.

With this solution, we could recognize $N$ as being the atomic number $Z$, where for progressively smaller fractions of $a_0$ we find an interesting proportional relationship between the holographic mass and the mass of the electron (see Figure 2).

From this holographic mass solution, we are thus able to calculate the total mass of the electrons for all known elements, without the need for adding the atomic mass number, $Z$. We instead find that the atomic mass number $Z$ could be a natural consequence of the holographic solution. As a result, a picture develops in which the structure of the Bohr atom and the charge and mass of both the proton and the electron are consequences of spin dynamics in the co-moving behaviour of the Planck scale granular structure of spacetime. This suggests that the confinement for the electron is a result of the quantum gravitational force exerted by the dynamics of the vacuum at the Planck scale. The electrostatic force can thus be accounted for in the same way the strong force is accounted for in the case of the proton [17] [18], where in both cases, the proton and the electron confinement is the result of a quantum force exerted through the granular Planck scale structure of spacetime.

5. Deriving the Rydberg constant, the fine structure constant and the proton to electron mass ratio

5.1 The Rydberg constant

The Rydberg constant is considered to be one of the most well-determined physical constants, with an accuracy of 7 parts to $10^{12}$ and is thus used to constrain the other physical constants [45]. However, as the same spectroscopic experiments are used to determine both the charge radius of the proton and the Rydberg constant, the recent muonic measurements of the charge radius of the proton implies that the Rydberg constant would change by $4 - 5\sigma$ [46] [47] [48]. This is known as the proton radius puzzle. The standard formula for the Rydberg constant is given as,
The electron and the holographic mass solution

Figure 2. Graph to show the holographic mass solution as a function of radius. Note: the holographic mass is equal to $m_e$ at corresponding radii of $a_0/N$. For example, the holographic mass: equals the mass of one electron at a radius of the hydrogen atom in its $n=1$ state; equals the mass of two electrons at a radius of the helium atom in its $n=1$ state; equals the mass of three electrons at a radius of the lithium atom in its $n=1$ state, and so on. Note this relationship is only shown on the graph for the first three elements but continues for all known elements.

\[
R_\infty = \frac{m_e \alpha^2 c}{2h}
\]  

(17)

so any change in the experimentally determined value for the proton radius and thus the Rydberg constant will have a significant effect on the constraints defining the relationships between $m_e$, $\alpha$, $c$ and $h$.

In order to understand and subsequently infer any discrepancies between experimental and theoretical values it is important to determine the underlying physical mechanism under which the Rydberg constant $R_\infty$ emerges. The holographic mass solution offers such a geometric mechanism providing a physical description and insight into how $R_\infty$ emerges.

The standard formula for the mass of the electron (Eqn. 1), can be reduced to,

\[
m_e = \frac{2R_\infty h}{c \alpha^2} = \frac{4\pi \ell m_e R_\infty}{\alpha^2}
\]  

(18)
Equating this (Eqn. 18) with the geometric solution (Eqn. 14) gives,

\[ m_e = \frac{4\pi\ell m_R}{\alpha^2} = \frac{1}{2\alpha\phi_c m_e} \]

and thus

\[ R_\infty = \frac{\alpha\phi_c}{8\pi\ell} = 1.097373(36) \times 10^5 \text{ cm}^{-1} \quad (19) \]

This definition offers a geometric solution for the Rydberg constant in agreement with the experimentally determined CODATA 2014 value.

As shown above, the holographic mass solution yields a correct value for both the charge radius of the proton, in agreement with the muonic radius measurement [17] [18] and the Rydberg constant independently, resolving the proton radius puzzle discrepancy from first principles.

5.2 The fine structure constant and the proton-to-electron mass ratio

This approach can as well be extended to derive the fine structure constant, \( \alpha \), and the proton to electron mass ratio, \( \mu \), in terms of \( \phi_e \).

If we equate the new geometric solution (Eqn. 19) with the standard definition (Eqn. 17) we get,

\[ R_\infty = \frac{m_e \alpha^2 c}{2h} = \frac{\alpha \phi_e}{8\pi\ell} \]

and thus

\[ \alpha = \frac{\phi_e h}{8\pi r_e m_e c} = \frac{\phi_e \lambda_e}{8\pi r_e} = 7.29735(34) \times 10^{-3} \quad (20) \]

which is in agreement with that of the CODATA 2014 value. The ratio of the proton mass to the electron mass, \( \mu \), can also be given in terms of the geometric solution (Eqn. 11 and Eqn. 14)

\[ \mu = \frac{m_p}{m_e} = \frac{2\phi m_e}{\phi m_e / 2\alpha} = 4\alpha \phi_e = 4 \alpha_0 = 1836.152(86) \quad (21) \]

A similar relationship, \( \frac{m_e}{m_p} \approx 10\alpha^2 \), was identified by Carr and Rees (1979) [49] (Eqn. 45) which they state is from a coincidence in nuclear physics and note that if the relation was not satisfied, elements vital to life would not exist [49].
6. Summary

A new derivation for the mass of the electron is presented from first principles, where the mass is defined in terms of the holographic surface-to-volume ratio and the relationship of the electric charge at the Planck scale to that at the electron scale. It should be emphasized that the generalized holographic approach is a new approach to quantum gravity based on geometrical considerations alone. It therefore does not utilize the established mathematics of quantum mechanics and general relativity to achieve its objectives. Interestingly and non-trivially, it is able to give a quantum analogy for the mass of the black hole – in that its mass is determined from discrete voxels of spacetime – and as well extends to the nucleon scale, where the mass of the proton and the electron can similarly be defined.

This new derivation for the electron extends the holographic mass solution to the hydrogen Bohr atom and for all known elements, defining the atomic structure and charge as a consequence of the electromagnetic fluctuation of the Planck scale. Furthermore, the atomic number, Z, emerges as a natural consequence of this geometric approach. The confinement for both the proton and the electron repulsive electrostatic force are now accounted for by a quantum gravitational force exerted by the granular Planck scale structure of spacetime. We conclude that this new approach offers an accurate value for the mass of the electron. As well, contrary to the standard calculation (as shown in Eqn. 1), it offers a physical understanding to the structure of spacetime at the quantum scale yielding significant insights in to the formation and source of the material world. Our results support our belief that such insights have significant value and should be developed further.

Acknowledgements

The authors would like to thank Prof. Bernard Carr, Dr. Robbert Dijkgraaf and Ulrich Winter for their invaluable comments and helpful discussions, Marshall Lefferts and Andy Day for the use of their diagram (Figure 1) and as well the ATINER for presenting the re-search in its preliminary stages at the 2015 satellite discussion meeting.
